Principle of automatic wind measurement for wind turbines

Overview

The article provides an overview of wind speed measurement in wind turbines, focusing on different types of anemometers and their working principles. Measurements of the SWiFT turbine wake from the DTU SpinnerLidar at 1-5 D ($D = 27$ m) Figure 8. The OpenLidar modular architecture enables collaboration and experimentation. A dual-Doppler-synthesized horizontal wind speed at hub height (A) with an algorithm-defined wake. Cup anemometer measurements are inherently biased due to the turbulent nature of the wind, but these errors can be neglected in many applications if a well-designed, fast-responding anemometer is used. Proper installation, calibration, and maintenance of the anemometer ensure reliable data. In addition, the performance test codes for wind turbines of the American Society of Mechanical Engineers and the measurement standards of the American Wind Energy Association contain much useful information on wind instrumentation equipment and procedures. By leveraging business intelligence and data analytics, organizations can ensure optimal performance, reduce downtimes, and enhance the overall.

Principle of automatic wind measurement for wind turbines

To maximize wind utilization, we propose to precisely measure the wind in a three-dimensional (3D) space, thus facilitating the process of wind turbine control.

Anemometer, The Essential Instrument for Measuring Wind Speed

2. How Does an Anemometer Work?
Anemometers operate by detecting changes in airflow velocity and pressure. Depending on the type, they may measure wind using mechanical, electrical, or optical ...

Wind measurements for wind energy applications. A review

Most wind measurements are performed using simple me-chemical devices, like the traditional cup anemometer. The behaviour of these is fairly well understood and the sources of error well known--b ...

Wind Speed Measurement and Instrumentation

The designs used for wind energy applications have a fast response and behave linearly in changing wind speeds. In a typical horizontal configuration, the propeller is kept facing the wind by a tail-vane, ...
