# **Why is the base station power supply 53V**

## Overview

---

A 53V DC power supply converts electrical energy from a source into a usable voltage for electronic devices. Modern FPGAs and processors are built using advanced nanometer processes because they often perform calculations at fast speeds using low voltages (<0.9 V) at high current from compact. Below is an overview of all 53V power supplies. However, due to the changes in AC voltage and load current, the DC voltage obtained after rectification usually causes a voltage change of 20% to 40%. In order to obtain a stable DC voltage, a voltage stabilization circuit must be used to. Power factor corrected (PFC) AC/DC power supplies with load sharing and redundancy (N+1) at the front-end feed dense, high efficiency DC/DC modules and point-of-load converters on the back-end.
